The authors would also like to thank Professors Esfandiar Maasoumi, Harry M. Markowitz, and Franco Pellerey for valuable comments that have significantly improved this manuscript. Our deepest thanks also go to Professor Juan Dubra for his helpful comments and assistance with the paper. The second author would like to thank Professors Robert B. Miller and Howard E. Thompson for their continuous guidance and encouragement. This research is partially supported by grants from Universidad de la Republica del Uruguay and Hong Kong Baptist University.

Gains from Diversification on Convex Combinations: A Majorization and Stochastic Dominance Approach

Abstract

By incorporating both majorization theory and stochastic dominance theory, this paper presents a general theory and a unifying framework for determining the diversification preferences of risk-averse investors and conditions under which they would unanimously judge a particular asset to be superior. In particular, we develop a theory for comparing the preferences of different convex combinations of assets that characterize a portfolio to give higher expected utility by second-order stochastic dominance. Our findings also provide an additional methodology for determining the second-order stochastic dominance efficient set.

Keywords: majorization; stochastic dominance; portfolio selection; expected utility; diversification

JEL Classification: D81, G11

1 Introduction

The pioneer work of Markowitz (1952) and Tobin (1958) on the mean-variance (MV) portfolio selection is a milestone in modern finance theory for optimal portfolio construction, asset allocation, and investment diversification.¹ In the procedure, investors respond to the uncertainty of an investment by selecting a portfolio that maximizes anticipated profit, subject to achieving a specified level of calculated risk or, equivalently, minimizes variance, subject to obtaining a predetermined level of expected gain. However, the disadvantage of using the MV criterion² is that it is derived by assuming the von Neumann-Morgenstern (1944) quadratic utility function and returns being examined are required to be normally distributed or elliptic distributed (Feldstein, 1969; Hanoch and Levy, 1969; Berk, 1997).

To circumvent the limitations of the MV criterion, academics recommend adopting the stochastic dominance (SD) approach, which can be used in constructing a general framework for the analysis of choice and problems of diversification for risk-averse investors under uncertainty without any restriction on the distribution of the assets being analyzed and without imposing the quadratic utility function assumption on investors. Academics have regarded the SD approach as one of the most useful tools for ranking uncertain investment prospects or portfolios because their rankings have been theoretically justified to be equal to the rankings of the corresponding expected utilities. Hanoch and Levy (1969) link stochastic dominance to a class of utility functions for non-satiable and risk-averse investors. Hadar and Russell (1971) develop the analysis using the concept of stochastic dominance and its applicability to choices under conditions of uncertainty,

¹To enhance the mean-variance portfolio selection, recently Leung and Wong (2008) apply the technique of the repeated measures design to develop a multivariate Sharpe ratio statistic to test the hypothesis of the equality of multiple Sharpe ratios, whereas Bai, et al. (2009a,b) develop new bootstrap-corrected estimations for the optimal return and its asset allocation and prove that these bootstrap-corrected estimates are proportionally consistent with their theoretic counterparts.

²This rule provides an excellent approximation to any risk averse utility function under some restrictions on the range of return; see Levy and Markowitz (1979) for more information.

whereas Tesfatsion (1976) further extends their results for diversification using a stochastic dominance approach to maximizing investors' expected utilities. Readers may refer to Ortobelli Lozza (2001) and Post (2008) for an exhaustive overview of other useful results along these lines.

By combining majorization theory with stochastic dominance theory, we extend the theory by developing some new results for choice in portfolio diversification. To specify, we establish some new theorems to determine the preferences of risk-averse investors among different diversified portfolios and show the conditions under which all risk-averse investors would prefer more diversified portfolios to less diversified ones. Our findings are important because they permit investors to specialize the rankings, by second-order stochastic dominance, from among a wide range of convex combinations of assets, and especially because they have implications concerning the weights of allocations. Our findings enable investors to make choices about allocations from their capital that result in higher expected utilities. This was one of the topics that Levy (2006) suggested for future research.

In addition, our findings could also be used in determining the second-order stochastic dominance efficient set. Traditionally, there are two decision stages in determining the efficient set; see Bawa et al. (1985). In the first stage, the initial screening of prospects or investments is accomplished by partitioning the feasible set into the efficient and inefficient sets using a stochastic dominance relation.³ At the second stage, Fishburn's (1974) concept of convex stochastic dominance (CSD) is used to eliminate elements that are not optimal in the sense of CSD. Alternatives that are dominated by convex combinations of other portfolios will be eliminated from the efficient set as they are classified to be inefficient. In this context, our findings allow investors to rank convex combinations of assets by majorization order, which, in turn, implies the rankings of their preferences of

³Readers may refer to Broll, et al. (2006), Wong (2006, 2007) and Wong and Chan (2008) and the references there for more information.

second-order stochastic dominance. Thus, our findings assist investors in determining the second-order stochastic dominance efficient set.

Our paper is organized as follows. We begin by introducing definitions and notations and stating some basic properties for the majorization theory and stochastic dominance theory. Section 3 presents our findings on the preferences for risk-averse investors in their choices of diversified portfolios, and Section 4 offers some conclusions.

2 Definitions and Notations

In this section, we will first introduce some notations and well-known properties in stochastic dominance theory and majorization theory that we will use in this paper. Considering an economic agent with unitary initial capital, in this paper we study the single-period portfolio selection for risk-averse investors to allocate their wealth to the n ($n > 1$) risks without short selling in order to maximize their expected utilities from the resulting final wealth. Let random variable X be an (excess) return of an asset or prospect. If there are n assets $\vec{X}_n = (X_1, \dots, X_n)'$,⁴ a portfolio of \vec{X}_n without short selling is defined by a convex combination, $\vec{\lambda}_n' \vec{X}_n$, of the n assets \vec{X}_n for any $\vec{\lambda}_n \in S_n^0$ where

$$S_n^0 = \left\{ (s_1, s_2, \dots, s_n)' \in \mathbb{R}^n : 0 \leq s_i \leq 1 \text{ for any } i, \sum_{i=1}^n s_i = 1 \right\} \quad (1)$$

in which \mathbb{R} is the set of real numbers. The i^{th} element of $\vec{\lambda}_n$ is the weight of the portfolio allocation on the i^{th} asset of return X_i . A portfolio will be equivalent to return on asset i if $s_i = 1$ and $s_j = 0$ for all $j \neq i$. It is diversified if there exists i such that $0 < s_i < 1$, and is completely diversified if $0 < s_i < 1$ for all $i = 1, 2, \dots, n$. As we study the properties of majorization in this context, without loss of generality, we further assume that S_n

⁴One could easily extend the theory developed in this paper to \vec{X}_∞ . We skip the discussion of theory for \vec{X}_∞ and restrict n to be a finite integer in this paper.

satisfies:

$$S_n = \left\{ (s_1, s_2, \dots, s_n)' \in \mathbb{R}^n : 1 \geq s_1 \geq s_2 \geq \dots \geq s_n \geq 0, \sum_{i=1}^n s_i = 1 \right\}. \quad (2)$$

We note that the condition of $\sum_{i=1}^n s_i = 1$ is not necessary. It could be any positive number in most of the findings in this paper. For convenience, we set $\sum_{i=1}^n s_i = 1$ so that the sum of all relative weights is equal to one. In this paper, we will mainly study the properties of majorization by considering $\vec{\lambda}_n \in S_n$ instead of S_n^0 .

Suppose that an investor has utility function u , and his/her expected utility for the portfolio $\vec{\lambda}_n' \vec{X}_n$ is $E[u(\vec{\lambda}_n' \vec{X}_n)]$. In this context, we study only the behavior of non-satiated and risk-averse investors whose utility functions belong to the following classes (see, for example, Ingersoll, 1987):

Definition 1⁵ U_2 is the set of the utility functions, u , defined in \mathbb{R} such that:

$$U_2 = \{u : (-1)^i u^{(i)} \leq 0, i = 1, 2\},$$

where $u^{(i)}$ is the i^{th} derivative of the utility function u , and the extended set of utility functions is:

$$U_2^E = \{u : u \text{ is increasing and concave}\}.$$

We note that in the above definition, “increasing” means “non-decreasing.” It is known (e.g., see Theorem 11C in Roberts and Varberg 1973) that u in U_2^E is differentiable almost everywhere and its derivative is continuous almost everywhere. We note that the theory can be easily extended to satisfy utilities defined in Definition 1 to be non-differentiable.⁶

⁵We note that if $u \in U_2$, u is Fréchet differentiable; see, for example, Machina (1982) for more information

⁶Readers may refer to Wong and Ma (2008) and the references there for more information. In this paper, we will skip the discussion of non-differentiable utilities.

There are many ways to order the elements in S_n . A popular one is to order them by majorization; see, for example, Hardy, et al. (1934) and Marshall and Olkin (1979), as stated in the following:

Definition 2 Let $\vec{\alpha}_n, \vec{\beta}_n \in S_n$ in which S_n is defined in (2). $\vec{\beta}_n$ is said to majorize $\vec{\alpha}_n$, denoted by $\vec{\beta}_n \succeq_M \vec{\alpha}_n$, if $\sum_{i=1}^k \beta_i \geq \sum_{i=1}^k \alpha_i$, for all $k = 1, 2, \dots, n$.

Majorization is a partial order among vectors of real numbers. We illustrate it in the following example:

Example 1 $(\frac{3}{5}, \frac{1}{5}, \frac{1}{5})' \succeq_M (\frac{2}{5}, \frac{2}{5}, \frac{1}{5})'$ because $\frac{3}{5} > \frac{2}{5}$ and $\frac{3}{5} + \frac{1}{5} \geq \frac{2}{5} + \frac{2}{5}$.

Vectors that can be ordered by majorization have some interesting properties. One of them is a Dalton Pigou transfer, as described in the following definition:

Definition 3⁷ For any $\vec{\alpha}_n, \vec{\beta}_n \in S_n$, $\vec{\alpha}_n$ is said to be obtained from $\vec{\beta}_n$ by applying a single Dalton (Pigou) transfer, denoted by $\vec{\beta}_n \xrightarrow{d} \vec{\alpha}_n$, if there exist h and k ($1 \leq h < k \leq n$) such that $\alpha_i = \beta_i$ for any $i \neq h, k$; $\alpha_h = \beta_h - \epsilon$; and $\alpha_k = \beta_k + \epsilon$ with $\epsilon > 0$.

For instance, consider the above example that $\vec{\alpha}_3 = (\frac{2}{5}, \frac{2}{5}, \frac{1}{5})'$ and $\vec{\beta}_3 = (\frac{3}{5}, \frac{1}{5}, \frac{1}{5})'$. As $\alpha_1 = \beta_1 - \frac{1}{5}$, $\alpha_2 = \beta_2 + \frac{1}{5}$, and $\alpha_3 = \beta_3 = \frac{1}{5}$, from Definition 3, we said that $\vec{\alpha}_3$ can be obtained from $\vec{\beta}_3$ by applying a single Dalton transfer by setting $\alpha_1 = \beta_1 - \frac{1}{5}$ and $\alpha_2 = \beta_2 + \frac{1}{5}$. Thus, we write $\vec{\beta}_3 \xrightarrow{d} \vec{\alpha}_3$.

In this example, we also notice that $\vec{\beta}_3$ majorizes $\vec{\alpha}_3$. One may wonder whether there is any relationship between majorization and a Dalton transfer. To answer this question, we have the following theorem:

Theorem 1 Let $\vec{\alpha}_n, \vec{\beta}_n \in S_n$, $\vec{\beta}_n \succeq_M \vec{\alpha}_n$ if and only if $\vec{\alpha}_n$ can be obtained from $\vec{\beta}_n$ by applying a finite number of Dalton transfers, denoted by $\vec{\beta}_n \xrightarrow{D} \vec{\alpha}_n$.

⁷Some academics suggest the reverse direction for the definition of a Dalton Pigou transfer. In this paper, we follow Ok and Kranich (1998) for the definition.

Readers may refer to Appendix 1 for the proof of Theorem 1. This theorem states that if $\vec{\beta}_n$ majorizes $\vec{\alpha}_n$, then $\vec{\alpha}_n$ can be obtained from $\vec{\beta}_n$ by applying a finite number of single Dalton transfers, and vice versa. We illustrate the procedure in the following example:

Example 2 Consider $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})'$ and $(\frac{4}{5}, \frac{1}{5}, 0)'$. As $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})'$ is majorized by $(\frac{4}{5}, \frac{1}{5}, 0)'$, from Theorem 1, we know that $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})'$ can be obtained by applying a finite number of single Dalton transfers on $(\frac{4}{5}, \frac{1}{5}, 0)'$. This could be done, for example, by setting $(\frac{4}{5}, \frac{1}{5}, 0)' \xrightarrow{d} (\frac{2}{3}, \frac{1}{3}, 0)' \xrightarrow{d} (\frac{1}{3}, \frac{1}{3}, \frac{1}{3})'$. That is, by simply first transferring $\frac{2}{15}$ from the first entry to the second entry of $(\frac{4}{5}, \frac{1}{5}, 0)'$ and then transferring $\frac{1}{3}$ from its first entry to its third entry to obtain $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})'$. Thus, we write $(\frac{4}{5}, \frac{1}{5}, 0)' \xrightarrow{D} (\frac{1}{3}, \frac{1}{3}, \frac{1}{3})'$.

In this paper, we link a Dalton transfer and majorization order to stochastic dominance. The theory of stochastic dominance is important in decision making, since the rankings of assets or portfolio preferences have been proved to be equivalent to the rankings of their corresponding expected utilities. Before we discuss stochastic dominance, we define some notations as follows. Let $\overline{\mathbb{R}}$ be the set of extended real numbers. Suppose that $\Omega = [a, b]$ is a subset of $\overline{\mathbb{R}}$ in which a and b can be finite or infinite. Let \mathbb{B} be the Borel σ -field of Ω and μ be a measure on (Ω, \mathbb{B}) . The function F of the measure μ is defined as:

$$F(x) = \mu(a, x] \quad \text{for all } x \in \Omega. \quad (3)$$

The function F is called a (probability) distribution function and μ is called a probability measure if $\mu(\Omega) = 1$. By the basic probability theory, for any random variable X and for probability measure P , there exists a unique induced probability measure μ on (Ω, \mathbb{B}) and the probability distribution function F such that F satisfies (3) and

$$\mu(B) = P(X^{-1}(B)) = P(X \in B) \quad \text{for any } B \in \mathbb{B}.$$

An integral written in the form of $\int_A f(t) d\mu(t)$ or $\int_A f(t) dF(t)$ is a Lebesgue-Stieltjes integral for any integrable function $f(t)$. If the integral has the same value for any set A

that is equal to $(c, d]$, $[c, d)$ or $[c, d]$, then we use the notation $\int_c^d f(t) d\mu(t)$ instead. In addition, if μ is a Borel measure with $\mu(c, d] = d - c$ for any $c < d$, then we write the integral as $\int_c^d f(t) dt$. The Lebesgue-Stieltjes integral $\int_c^d f(t) dt$ is equal to the Riemann integral if f is bounded and continuous almost everywhere on $[c, d]$; see Theorem 1.7.1 in Ash (1972).

We consider random variables, denoted by X, Y, \dots defined on Ω . The probability distribution functions of X and Y are F and G , respectively. Throughout this paper, all functions are assumed to be measurable, and all integrals and expectations are implicitly assumed to exist and to be finite. We next define the second-order stochastic dominance that will be useful for risk-averse investors in making their decision as follows:

Definition 4 *Given two random variables X and Y with F and G as their respective probability distribution functions defined on $[a, b]$, X dominates Y and F dominates G in the sense of SSD, denoted by $X \succeq_2 Y$ or $F \succeq_2 G$, if and only if $\int_a^x F(y) dy \leq \int_a^x G(y) dy$ for each x in $[a, b]$, where SSD stands for second-order stochastic dominance.*

An individual chooses between F and G in accordance with a consistent set of preferences satisfying the von Neumann-Morgenstern (1944) consistency properties. Accordingly, F is preferred to G , or equivalently, X is preferred to Y for all utility functions u if

$$\Delta Eu \equiv E[u(X)] - E[u(Y)] \geq 0, \quad (4)$$

where $E[u(X)] \equiv \int_a^b u dF$ and $E[u(Y)] \equiv \int_a^b u dG$.

3 The Theory

In this section, we will develop the theory of diversification for risk-averse investors to make comparisons among different portfolios by incorporating both majorization theory and stochastic dominance theory.

We first discuss the stochastic dominance theory for random variables, and non-negative combinations, or equivalently convex combinations, of random variables. Random variables X, Y, \dots can be regarded as returns on individual prospects, and convex combinations of random variables can be regarded as the returns on the portfolios for different prospects. Hence, stochastic dominance for the random variables can be applied to examine preferences of different prospects and the preferences of different portfolios. The theory of stochastic dominance is important because it is equivalent to the theory of utility maximization as stated in the following theorem:

Theorem 2 *Let X and Y be random variables with probability distribution functions F and G , respectively. Suppose u is a utility function. Then,*

$$X \succeq_2 Y \text{ or, equivalently, } F \succeq_2 G \text{ if and only if } E[u(X)] \geq E[u(Y)]$$

for any $u \in U_2^E$.

We note that Hanoch and Levy (1969) and Hadar and Russell (1969) first prove this theorem. Readers may refer to their papers for the proof of the theorem.

Hadar and Russell (1971) first investigate the diversification problem for the independent and identically distributed (iid) case in a bivariate setting. They verify that

$$E[u(\vec{\alpha}_2' \vec{X}_2)] \geq E[u(\vec{\beta}_2' \vec{X}_2)] \tag{5}$$

whenever $|\alpha_1 - \alpha_2| \leq |\beta_1 - \beta_2|$ where $\vec{\alpha}_2 = (\alpha_1, \alpha_2)'$ and $\vec{\beta}_2 = (\beta_1, \beta_2)' \in S_2$, $u \in U_2$, and $\vec{X}_2 = (X_1, X_2)'$ in which X_1 and X_2 are non-negative independent and identically distributed random variables.

We note that for any pair of random variables X and Y , the statements $X \succeq_2 Y$ and $F \succeq_2 G$ are equivalent. But for $n > 1$, the statements $\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{Y}_n$ and $\vec{\alpha}'_n \vec{F}_n \succeq_2$

$\vec{\beta}'_n \vec{G}_n$ ⁸ are different because the distribution functions of $\vec{\alpha}'_n \vec{X}_n$ and $\vec{\beta}'_n \vec{Y}_n$ are different from $\vec{\alpha}'_n \vec{F}_n$ and $\vec{\beta}'_n \vec{G}_n$, respectively. Thus, we cannot apply the convex stochastic dominance theorems obtained in Fishburn (1974), Dekel (1989), and Wong and Li (1999) to the convex combinations of random variables. To investigate the properties of the convex combinations of random variables, Hadar and Russell (1971) and Tesfatsion (1976) first study the invariance property of the stochastic dominance for the convex combinations of random variables in a bivariate setting, whereas Li and Wong (1999) further extend their work by comparing two sets of independent variables in a multivariate setting as shown in the following theorem:

Theorem 3 For $n > 1$, let $\vec{X}_n = (X_1, \dots, X_n)'$ and $\vec{Y}_n = (Y_1, \dots, Y_n)'$ where $\{X_1, \dots, X_n\}$ and $\{Y_1, \dots, Y_n\}$ be two sets of independent and identically distributed random variables. Then, $X_i \succeq_2 Y_i$ for any $i = 1, 2, \dots, n$ if and only if $\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\alpha}'_n \vec{Y}_n$ for any $\vec{\alpha}_n \in S_n^0$.

One may refer to Li and Wong (1999) for the proof. We provide the following example to illustrate Theorem 3:

Example 3 Consider Y_i to be independently distributed with zero mean and unit variance, and $X_i = a + bY_i$ with $a \geq 0$ and $0 < b \leq 1$ for any $i = 1, \dots, n$. Applying Theorem 8 in Li and Wong (1999), one could show that $X_i \succeq_2 Y_i$ for any $i = 1, 2, \dots, n$. Thereafter, applying Theorem 3, one could obtain $\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\alpha}'_n \vec{Y}_n$ for any $\vec{\alpha}_n \in S_n^0$.

Let $\left(\frac{1}{n}\right) = \left(\frac{1}{n}, \dots, \frac{1}{n}\right)'$. Hanoch and Levy (1969), Hadar and Russell (1971), and Tesfatsion (1976) verify in the bivariate case that, for any $\left(\frac{1}{2}\right)$ and $\vec{\alpha}_2 \in S_2^0$, if X_1 and X_2 are independent and identically distributed, then

$$\left(\frac{1}{2}\right)' \vec{X}_2 \succeq_2 \vec{\alpha}'_2 \vec{X}_2 \succeq_2 X_i \text{ for } i = 1, 2.$$

⁸ $\vec{X}_n = (X_1, \dots, X_n)'$, $\vec{Y}_n = (Y_1, \dots, Y_n)'$, $\vec{F}_n = (F_1, \dots, F_n)'$ and $\vec{G}_n = (G_1, \dots, G_n)'$ where F_i and G_i are the distribution functions of X_i and Y_i , respectively.

Li and Wong (1999) generalize the results further to the case of random variables in a multivariate setting as shown in the following theorem:

Theorem 4 For $n > 1$, let $\vec{X}_n = (X_1, \dots, X_n)'$ where X_1, \dots, X_n are independent and identically distributed, then, for any $i = 1, 2, \dots, n$ and for any $(\frac{\vec{1}}{n})$, $\vec{\alpha}_n \in S_n^0$,

$$\left(\frac{\vec{1}}{n}\right)' \vec{X}_n \succeq_2 \vec{\alpha}_n' \vec{X}_n \succeq_2 X_i.$$

Readers may refer to Li and Wong (1999) for the proof of Theorem 4. We note that Samuelson (1967) has proved that $(\frac{\vec{1}}{n})' \vec{X}_n$ attains maximum among $\vec{\alpha}_n' \vec{X}_n$ for any iid non-negative X_i . This theorem verifies the optimality of diversification that the maximal expected utility will be achieved in an equally weighted portfolio of independent and identically distributed assets. The manifestation of the generality of the theorem is that it places very weak restrictions on the weights. This theorem implies that for independent and identically distributed assets, risk-averse investors will prefer the equally weighted portfolio to any convex combination portfolio, which, in turn, is preferred to any individual asset.

Nonetheless, Theorem 4 does not permit investors to compare the preferences of other different convex combinations of random variables. So far, the comparison of the preferences of different convex combinations of random variables has not been well studied in the literature. To bridge the gap in the literature, in this paper we will develop a theory to compare the preferences of different convex combinations of random variables. We first examine the situation in which the underlying assets are independent and identically distributed. To make our contribution clear, we first state the situation in a bivariate setting as shown in the following theorem:

Theorem 5 Let $\vec{\alpha}_2, \vec{\beta}_2 \in S_2$ and $\vec{X}_2 = (X_1, X_2)'$ where X_1 and X_2 are independent and identically distributed. Then,

$$\vec{\beta}_2 \succeq_M \vec{\alpha}_2 \text{ if and only if } \vec{\alpha}_2' \vec{X}_2 \succeq_2 \vec{\beta}_2' \vec{X}_2.$$

The proof of Theorem 5 is in the appendix. This theorem provides a methodology for investors to make comparisons among a wide range of portfolios so that they make better choices in their investment decisions, especially the implications concerning the weights of allocations.

It is interesting to note from Theorem 1 that, if $\vec{\alpha}_2$ is majorized by $\vec{\beta}_2$, $\vec{\alpha}_2$ can be obtained from vector $\vec{\beta}_2$ by applying Dalton transfer(s) and vice versa. Thus, we could incorporate Theorem 1 into Theorem 5 to obtain the following corollary:

Corollary 6 *Let $\vec{\alpha}_2, \vec{\beta}_2 \in S_2$ and $\vec{X}_2 = (X_1, X_2)'$ where X_1 and X_2 are independent and identically distributed. Then,*

$$\vec{\beta}_2 \xrightarrow{D} \vec{\alpha}_2 \quad \text{if and only if} \quad \vec{\alpha}'_2 \vec{X}_2 \succeq_2 \vec{\beta}'_2 \vec{X}_2.$$

Theorem 5 and Corollary 6 extend the results developed by Hadar and Russell (1971), Tesfatsion (1976), and Li and Wong (1999). In this context, we further generalize the above results to a multivariate setting as shown in the following theorem:

Theorem 7 *For $n > 1$, let $\vec{\alpha}_n, \vec{\beta}_n \in S_n$ ⁹ and $\vec{X}_n = (X_1, \dots, X_n)'$ where X_1, \dots, X_n are independent and identically distributed. If $\vec{\beta}_n \succeq_M \vec{\alpha}_n$, then $\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{X}_n$.*

The proof of Theorem 7 is in the appendix. The relationship between stochastic dominance and majorization order characterized by this theorem allows us to rank different convex combinations of two sets of independent and identically distributed assets in a multivariate setting. It conveys two messages to investors: First, any risk-averse investor will always prefer portfolios with majorized vectors of allocations to ones with majorizing vectors of allocations. Second, if $\vec{\alpha}_n$ and $\vec{\beta}_n$ cannot be ranked by majorization, the port-

⁹We keep the condition $\sum_{i=1}^n s_i = 1$ in S_n for convenience. One could exclude this condition and relax it to be $\vec{1}'_n \vec{\alpha}_n = \vec{1}'_n \vec{\beta}_n$.

folios $\vec{\alpha}'_n \vec{X}_n$ and $\vec{\beta}'_n \vec{X}_n$ could be SSD incomparable.¹⁰ Further investigation of their SSD determination is required.

In addition, incorporating Theorem 1 into Theorem 7, we obtain the following corollary:

Corollary 8 For $n > 1$, let $\vec{\alpha}_n, \vec{\beta}_n \in S_n$ and $\vec{X}_n = (X_1, \dots, X_n)$ where X_1, \dots, X_n are independent and identically distributed. If $\vec{\beta}_n \xrightarrow{D} \vec{\alpha}_n$, then $\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{X}_n$.

We note that the necessary condition of Theorem 5 and Corollary 6 can only hold in a bivariate setting and not in a multivariate setting. We illustrate by the following example that the converse of Theorem 7 does not hold:

Example 4 Consider $U = \frac{1}{2}X_1 + \frac{1}{2}X_2$ and $V = \frac{3}{4}X_1 + \frac{1}{8}X_2 + \frac{1}{8}X_3$ where X_i ($i = 1, 2, 3$) is independent and identically distributed as $N(0, 1)$. One can easily show that $U \succeq_2 V$ as $E(U) = E(V)$ and $Var(U) < Var(V)$. Nonetheless, $(\frac{1}{2}, \frac{1}{2}, 0)'$ and $(\frac{3}{4}, \frac{1}{8}, \frac{1}{8})'$ cannot be ordered by majorization.

Similarly, one could easily construct an example to show that the necessary condition of Corollary 8 does not hold in a multivariate setting. Theorem 7 and Corollary 8 further extend the results developed by Hadar and Russell (1971), Tesfatsion (1976), and Li and Wong (1999) by providing an additional methodology for investors to make comparisons among a wide range of different convex combinations of assets in a multivariate setting to check their SSD preferences. These results are very useful. They permit investors to rank different convex combinations of independent and identically distributed random variables by second-order stochastic dominance and by their corresponding vectors of allocations. Since the portfolios with majorizing vectors will be second-order stochastically dominated

¹⁰ X and Y are SSD comparable if either $X \succeq_n Y$ or $Y \succeq_n X$ holds, and X and Y are not SSD comparable, or are SSD incomparable, if both $X \not\succeq_n Y$ and $Y \not\succeq_n X$ hold, where $X \not\succeq_n Y$ means $X \succeq_n Y$ does not hold.

by the ones with majorized vectors, those with majorizing vectors should be eliminated from the SSD efficient set. Thus, our findings could be used in determining the second-order stochastic dominance efficient set. We illustrate how to compare different portfolios in the following example:

Example 5 *Suppose that one would like to rank the following assets by second-order stochastic dominance: $\vec{\alpha}'_3 \vec{X}_3 = \frac{2}{5}X_1 + \frac{2}{5}X_2 + \frac{1}{5}X_3$ and $\vec{\beta}'_3 \vec{X}_3 = \frac{3}{5}X_1 + \frac{1}{5}X_2 + \frac{1}{5}X_3$. One could achieve the objective simply by examining the majorization orders. In this example, one could easily find that $\vec{\beta}_3$ majorizes $\vec{\alpha}_3$ (see Example 1). Thereafter, applying Theorem 7, we obtain $\vec{\alpha}'_3 \vec{X}_3 \succeq_2 \vec{\beta}'_3 \vec{X}_3$.*

If one does not want to apply Theorem 7 directly, one could consider applying Theorem 3 and Theorem 5 instead. We illustrate the procedure as follows: By Theorem 5, we know that since $(\frac{3}{5}, \frac{1}{5}, 0)'$ majorizes $(\frac{2}{5}, \frac{2}{5}, 0)'$ ¹¹, and we have $\frac{2}{5}X_1 + \frac{2}{5}X_2 \succeq_2 \frac{3}{5}X_1 + \frac{1}{5}X_2$. By Theorem 3, adding another independent random variable, say $\frac{1}{5}X_3$, on both sides of the above does not alter the stochastic dominance relationship. Thus, we have $\frac{2}{5}X_1 + \frac{2}{5}X_2 + \frac{1}{5}X_3 \succeq_2 \frac{3}{5}X_1 + \frac{1}{5}X_2 + \frac{1}{5}X_3$.

Can the iid assumption be dropped in the diversification problem and the completely diversified portfolio still be optimal? Samuelson (1967) tells us that the answer is no in general. He further establishes some results to relax the iid assumption. In this paper, we complement Samuelson's work by extending the results stated in the above theorems and corollaries by relaxing the independent and identically distributed condition as stated in the following corollaries:

Corollary 9 *For $n > 1$, let $\vec{X}_n = (X_1, \dots, X_n)'$ be a series of random variables that*

¹¹Readers may refer to footnote 9 to see that it is not necessary for the sum of all weights in the vectors to be 1. As long as the summations of the weights are equal for all portfolios being compared, the results for Theorem 7 hold.

could be dependent. For any $\vec{\alpha}_n$ and $\vec{\beta}_n$,

$$\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{X}_n$$

if there exist \vec{Y}_n and A_{nn} such that $\vec{Y}_n = (Y_1, \dots, Y_n)'$ in which $\{Y_1, \dots, Y_n\}$ are independent and identically distributed, $\vec{X}_n = A_{nn} \vec{Y}_n$, and

$$\vec{\beta}'_n A_{nn} \succeq_M \vec{\alpha}'_n A_{nn},$$

where $\vec{\alpha}'_n A_{nn}, \vec{\beta}'_n A_{nn} \in S_n$.

Corollary 10 For $n > 1$, let $\vec{X}_n = (X_1, \dots, X_n)'$ and $\vec{Y}_n = (Y_1, \dots, Y_n)'$ be two series of random variables that could be dependent. For any $\vec{\alpha}_n$ and $\vec{\beta}_n$,

$$\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{Y}_n$$

if there exist $\vec{U}_n = (U_1, \dots, U_n)'$, $\vec{V}_n = (V_1, \dots, V_n)'$, A_{nn} , and B_{nn} in which $\{U_1, \dots, U_n\}$ and $\{V_1, \dots, V_n\}$ are two series of independent and identically distributed random variables such that $\vec{X}_n = A_{nn} \vec{U}_n$, $\vec{Y}_n = B_{nn} \vec{V}_n$, $U_i \succeq_2 V_i$ for all $i = 1, 2, \dots, n$; and

$$\vec{\beta}'_n B_{nn} \succeq_M \vec{\alpha}'_n A_{nn},$$

where $\vec{\alpha}'_n A_{nn}, \vec{\beta}'_n B_{nn} \in S_n$.

One could simply apply Theorem 7 to obtain the results of Corollary 9 and apply Theorem 3 to obtain the results of Corollary 10. One could then apply Theorem 1 to the above corollaries to obtain the following results:

Corollary 11 For $n > 1$, let $\vec{X}_n = (X_1, \dots, X_n)'$ be a series of random variables that could be dependent. For any $\vec{\alpha}_n$ and $\vec{\beta}_n$,

$$\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{X}_n$$

if there exist \vec{Y}_n and A_{nn} such that $\vec{Y}_n = (Y_1, \dots, Y_n)'$ in which $\{Y_1, \dots, Y_n\}$ are independent and identically distributed, $\vec{X}_n = A_{nn}\vec{Y}_n$, and

$$\vec{\beta}'_n A_{nn} \xrightarrow{D} \vec{\alpha}'_n A_{nn},$$

where $\vec{\alpha}'_n A_{nn}, \vec{\beta}'_n A_{nn} \in S_n$.

Corollary 12 For $n > 1$, let $\vec{X}_n = (X_1, \dots, X_n)'$ and $\vec{Y}_n = (Y_1, \dots, Y_n)'$ be two series of random variables that could be dependent. For any $\vec{\alpha}_n$ and $\vec{\beta}_n$,

$$\vec{\alpha}'_n \vec{X}_n \succeq_2 \vec{\beta}'_n \vec{Y}_n$$

if there exist $\vec{U}_n = (U_1, \dots, U_n)'$, $\vec{V}_n = (V_1, \dots, V_n)'$, A_{nn} , and B_{nn} in which $\{U_1, \dots, U_n\}$ and $\{V_1, \dots, V_n\}$ are two series of independent and identically distributed random variables such that $\vec{X}_n = A_{nn}\vec{U}_n$, $\vec{Y}_n = B_{nn}\vec{V}_n$, $U_i \succeq_2 V_i$ for all $i = 1, 2, \dots, n$; and

$$\vec{\beta}'_n B_{nn} \xrightarrow{D} \vec{\alpha}'_n A_{nn},$$

where $\vec{\alpha}'_n A_{nn}, \vec{\beta}'_n B_{nn} \in S_n$.

We provide the following examples to illustrate the usefulness of the above corollaries.

Example 6 Let Y_1, Y_2 and Y_3 be independent and identically distributed random variables. Consider $X_1 = \frac{3}{5}Y_1 + \frac{1}{5}Y_2 + \frac{1}{5}Y_3$, $X_2 = \frac{1}{3}Y_1 + \frac{1}{3}Y_2 + \frac{1}{3}Y_3$, and $X_3 = \frac{3}{4}Y_1 + \frac{1}{8}Y_2 + \frac{1}{8}Y_3$. Obviously, $\{X_i\}$ ($i = 1, 2, 3$) are dependent. Corollary 9 ensures that $\vec{\alpha}'_3 \vec{X}_3 \succeq_2 \vec{\beta}'_3 \vec{X}_3$ where $\vec{\alpha}_3 = (\frac{4}{5}, \frac{1}{10}, \frac{1}{10})'$, $\vec{\beta}_3 = (\frac{5}{6}, \frac{1}{12}, \frac{1}{12})'$, and $\vec{X}_3 = (X_1, X_2, X_3)'$. It is because one could easily find

$$A_{33} = \begin{bmatrix} \frac{3}{5} & \frac{1}{5} & \frac{1}{5} \\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \frac{3}{4} & \frac{1}{8} & \frac{1}{8} \end{bmatrix}$$

such that

$$\vec{\beta}'_3 A_{33} \succeq_M \vec{\alpha}'_3 A_{33}$$

and $\vec{\alpha}'_3 A_{33}, \vec{\beta}'_3 A_{33} \in S_3$.

In addition, one could also apply Corollary 11 to ensure $\vec{\alpha}'_3 \vec{X}_3 \succeq_2 \vec{\beta}'_3 \vec{X}_3$ as one could easily observe that

$$\vec{\beta}'_n A_{nn} \xrightarrow{D} \vec{\alpha}'_n A_{nn}.$$

Example 7 Let $\{V_i\}$ ($i = 1, 2, 3$) be a series of independent and identically distributed random variables with mean μ_V and variance σ_V^2 , respectively. Let $U_i = p + qV_i$ ($i = 1, 2, 3$) such that $0 \leq q < 1$ and $p/(1 - q) \geq \mu_V$. Then, by Theorem 8 in Li and Wong (1999), we have $U_i \succeq_2 V_i$ ($i = 1, 2, 3$).

Let $X_1 = \frac{1}{2}U_1 + \frac{1}{4}U_2 + \frac{1}{4}U_3$, $X_2 = \frac{1}{4}U_1 + \frac{1}{3}U_2 + \frac{5}{12}U_3$, $X_3 = \frac{1}{6}U_1 + \frac{1}{2}U_2 + \frac{1}{3}U_3$, $Y_1 = \frac{1}{3}V_1 + \frac{1}{3}V_2 + \frac{1}{3}V_3$, $Y_2 = \frac{4}{7}V_1 + \frac{1}{4}V_2 + \frac{5}{28}V_3$, and $Y_3 = \frac{4}{5}V_1 + \frac{4}{25}V_2 + \frac{1}{25}V_3$. Obviously, $\{X_i\}$ and $\{Y_i\}$ ($i = 1, 2, 3$) are dependent.

Corollary 10 ensures that $\vec{\alpha}'_3 \vec{X}_3 \succeq_2 \vec{\beta}'_3 \vec{Y}_3$ where $\alpha_3 = (\frac{2}{3}, \frac{1}{6}, \frac{1}{6})'$, $\beta_3 = (\frac{3}{4}, \frac{1}{8}, \frac{1}{8})'$, $\vec{X}_3 = (X_1, X_2, X_3)'$, and $\vec{Y}_3 = (Y_1, Y_2, Y_3)'$. It is because one could easily find

$$A_{33} = \begin{bmatrix} \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ \frac{1}{4} & \frac{1}{3} & \frac{5}{12} \\ \frac{1}{6} & \frac{1}{2} & \frac{1}{3} \end{bmatrix} \quad \text{and} \quad B_{33} = \begin{bmatrix} \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \\ \frac{4}{7} & \frac{1}{4} & \frac{5}{28} \\ \frac{4}{5} & \frac{4}{25} & \frac{1}{25} \end{bmatrix}$$

such that

$$\beta'_3 B_{33} \succeq_M \alpha'_3 A_{33}$$

and $\vec{\alpha}'_3 A_{33}, \vec{\beta}'_3 B_{33} \in S_3$.

In addition, one could also apply Corollary 12 to ensure $\vec{\alpha}'_3 \vec{X}_3 \succeq_2 \vec{\beta}'_3 \vec{Y}_3$ as one could easily find that

$$\vec{\beta}'_3 B_{33} \xrightarrow{D} \vec{\alpha}'_3 A_{33}.$$

As a consequence of the above corollaries, an additional methodology is provided by which investors can make comparisons among a wide range of different convex combina-

tions of dependent assets in a multivariate setting to check their SSD preferences. The results allow investors to rank different convex combinations of dependent assets not only by second-order stochastic dominance but also by their corresponding vectors of allocations. Our results also permit investors to eliminate non-efficient portfolios so that our results could help investors in determining the second-order stochastic dominance efficient set.

4 Concluding Remarks

By incorporating the majorization theory, this paper presents several new results of interest on stochastic dominance. Specifically, we establish some basic relationships in the portfolio choice problem by using both majorization theory and stochastic dominance. We also provide the foundation for applying majorization theory and stochastic dominance to investors' choices under uncertainty. The results are general, but presumably they are applicable to investment decision theory and comparisons of diversification of assets in a multivariate setting. We give new conditions for stochastic comparisons among different portfolio choices and new necessary and sufficient conditions that characterize diversified portfolios to give higher expected utilities. Thus, risk-averse and non-satiable investors will increase their expected utilities as the diversification of the portfolio increases. Our findings bring together, under a common framework, a number of fairly general results about diversification that permit comparisons among them. Our results could also be used to demonstrate the optimality of diversification and to obtain the preference orderings of portfolios for different asset allocations. In addition, our findings also impose further restrictions on admissible portfolios on the efficient frontier, and thus, our findings could also be used in determining the second-order stochastic dominance efficient set.

Nonetheless, Rothschild and Stiglitz (1970) show that for any two distributions with the same mean, the mean-preserving spread and SSD are equivalent, whereas Shalit and Yitzhaki (1994) verify that under some conditions, marginal conditional stochastic dom-

inance is equivalent to SSD. Thus, incorporating the theory developed in our paper, one could conclude that under some regularity conditions, the preferences obtained from a Dalton transfer, majorization, and stochastic dominance could be equivalent to those obtained from the mean-preserving spread and marginal conditional stochastic dominance.

Unlike the SD approach, which is consistent with utility maximization, the dominance findings using the mean-variance criterion¹² may not be consistent with utility maximization if the assets returns are not normally distributed or investors' utilities are not quadratic. However, under some specific conditions, the mean-variance optimality could be consistent with the SD approach with utility maximization. For example, Meyer (1987), Wong (2006, 2007) and Wong and Ma (2008) have shown that if the returns of assets follow the same location-scale family, then a mean-variance domination could infer preferences by risk averters for the dominant fund over the dominated one. In addition, the Markowitz mean-variance optimization is equivalent to minimizing variance subject to obtaining a predetermined level of expected gain; see, for example, Bai, et al. (2009a,b). Thus, by incorporating the results developed in this paper and under some regularity conditions, the efficient set derived from a Dalton transfer, majorization, and stochastic dominance could belong to the same efficient set obtained from the mean-variance criterion and risk minimization. Further research could study their relationships in detail.

Last, we note that, recently, other studies have findings that extend the bivariate framework of the diversification of risky assets to a multivariate setting. For example, Ma (2000) has removed the assumption of independence and studied the possibility that the random variables are exchangeable. In addition, Pellerrey and Semeraro (2005) derive some new results for the portfolio choice problem when risky opportunities are correlated. They give new conditions for stochastic comparison among different portfolio choices and new necessary and sufficient conditions that characterize the portfolio to give the maximal

¹²See, for example, Markowitz (1952), Joro and Na (2006), Buckley, et al. (2008), Josa-Fombellida and Rincón-Zapatero (2008), Zhao and Ziemba (2008) for more information.

expected utility. One avenue for further research would be to incorporate the findings in our paper to extend the results developed by Ma (2000), Pellerey and Semeraro (2005), and others. Since the theoretical results proved in this paper open the door for the development of real-life applications, another avenue for further research would apply the theory developed in this paper to different real-life applications in business, economics and finance. For example, one could incorporate the theory in this paper to explain well-known financial phenomena or financial anomalies¹³ and to model investment risk.¹⁴

Appendices

Appendix 1 : Proof of Theorem 1

Let $\Lambda_m = \{i_1, i_2, \dots, i_m\} \subseteq \Lambda_n = \{1, 2, \dots, n\}$ such that $\alpha_j \neq \beta_j$ for any $j \in \Lambda_m$ and $\alpha_j = \beta_j$ for any $j \in \Lambda_n \setminus \Lambda_m$. Then, we have $1 \geq \alpha_{i_1} \geq \alpha_{i_2} \geq \dots \geq \alpha_{i_m} \geq 0$, $1 \geq \beta_{i_1} \geq \beta_{i_2} \geq \dots \geq \beta_{i_m} \geq 0$, and $\sum_{j=1}^k \alpha_{i_j} \leq \sum_{j=1}^k \beta_{i_j}$ for any $k = 1, 2, \dots, m$.

Let $\delta_{i_j} = \beta_{i_j} - \alpha_{i_j}$ for $j = 1, 2, \dots, m$ and let p and q be the indices such that $|\delta_p| = \min\{|\delta_{i_j}| : j = 1, \dots, m\}$ and $|\delta_q| = \max\{|\delta_{i_j}| : j = 1, \dots, m\}$. Without loss of generality, we assume $p < q$. In this situation, one can easily show that $\delta_p = \beta_p - \alpha_p > 0$.

Let $\epsilon = \delta_p$ and $\vec{\gamma}_n = (\gamma_1, \dots, \gamma_n)'$ such that $\gamma_p = \beta_p - \epsilon$, $\gamma_q = \beta_q + \epsilon$, and $\gamma_i = \beta_i$ for any $i \neq p, q$. Then, we have $\vec{\beta}_n \xrightarrow{d} \vec{\gamma}_n$ by performing one Dalton transfer and now only $m - 1$ items of $\vec{\gamma}_n$ are different from those of $\vec{\alpha}_n$. One could simply continue this process $m - 2$ times to obtain $\vec{\alpha}_n$ from $\vec{\gamma}_n$. Thus, we have $\vec{\beta}_n \xrightarrow{D} \vec{\alpha}_n$ by performing $m - 1$ times single Dalton transfers. The assertion follows. □

Appendix 2 : Proof of Theorem 5

Before we prove Theorem 5, we first state the following lemma:

Lemma 13 For $n > 1$, suppose $u \in U_2$ defined in (1) and $Y = \sum_{i=1}^n \lambda_i X_i$ with $\sum_{i=1}^n \lambda_i = 1$ where X_1, \dots, X_n are random variables, then

$$E[u(Y)] \geq \sum_{i=1}^n \lambda_i E[u(X_i)].$$

Proof:

Let $F_{\vec{X}} = F_{X_1 X_2 \dots X_n}$ be the joint distribution function of $\{X_i\}$ defined on $\Lambda = \prod_{i=1}^n \Lambda_i$. As $u \in U_2$, for any $\vec{x} = (x_1, x_2, \dots, x_n)'$, by Jensen inequality, we have

$$u\left(\sum_{i=1}^n \lambda_i x_i\right) \geq \sum_{i=1}^n \lambda_i u(x_i). \quad (6)$$

Taking integration on both sides of (6) with respect to $F_{\vec{X}}$ on Λ , we have

$$\begin{aligned} \int_{\Lambda} u\left(\sum_{i=1}^n \lambda_i x_i\right) dF_{\vec{X}} &\geq \int_{\Lambda} \sum_{i=1}^n \lambda_i u(x_i) dF_{\vec{X}} \\ &= \sum_{i=1}^n \lambda_i \int_{\Lambda} u(x_i) dF_{\vec{X}} \\ &= \sum_{i=1}^n \lambda_i E[u(X_i)]. \end{aligned}$$

Thus, the assertion of Lemma 13 follows. □

Now we prove Theorem 5. We first prove the sufficient part of the theorem. Let $X = \vec{\alpha}'_2 \vec{X}_2$ and $Y = \vec{\beta}'_2 \vec{X}_2$ with distribution functions F and G , respectively. By Theorem

2, proving $X \succeq_2 Y$ is equivalent to proving that for any $u \in U_2$,

$$\Delta Eu \equiv Eu(X) - Eu(Y) = \int_a^b u(x)dF(x) - \int_a^b u(x)dG(x) \geq 0.$$

First, it is easy to verify that if $\vec{\beta}_2$ majorizes $\vec{\alpha}_2$, then there exists $\lambda \in (0, 1)$ such that

$$X = \lambda Y + (1 - \lambda) \left(\frac{X_1 + X_2}{2} \right). \quad (7)$$

Together with the concavity property of u as shown in Lemma 13, we have

$$\begin{aligned} E[u(X)] &= E \left\{ u \left[\lambda Y + (1 - \lambda) \left(\frac{X_1 + X_2}{2} \right) \right] \right\} \\ &\geq \lambda E[u(Y)] + (1 - \lambda) E \left[u \left(\frac{X_1 + X_2}{2} \right) \right]. \end{aligned}$$

As $\frac{1}{2} \vec{X}_2 \succeq_2 \vec{\lambda}' \vec{X}_2$ where $\vec{\lambda} = (\lambda, 1 - \lambda)'$, we have

$$\begin{aligned} \lambda E[u(Y)] + (1 - \lambda) E \left[u \left(\frac{1}{2} (X_1 + X_2) \right) \right] &\geq \lambda E[u(Y)] + (1 - \lambda) E[u(Y)] \\ &= E[u(Y)]. \end{aligned}$$

Thus, we have $E[u(X)] \geq E[u(Y)]$; and thereafter, $\Delta Eu \geq 0$ is obtained as required.

We now proceed to prove the necessary part of the theorem by contradiction. Suppose that $\vec{\alpha}'_2 \vec{X}_2 \succeq_2 \vec{\beta}'_2 \vec{X}_2$ but $\vec{\beta}_2$ does not majorize $\vec{\alpha}_2$. Then, there are two cases for $\vec{\beta}_2$ not to majorize $\vec{\alpha}_2$ as follows:

1. $\vec{\alpha}_2$ majorizes $\vec{\beta}_2$, or
2. $\vec{\alpha}_2$ and $\vec{\beta}_2$ are not comparable by majorization.

In the first case that $\vec{\alpha}_2$ majorizes $\vec{\beta}_2$. By the sufficient part of this theorem, we have $\vec{\beta}'_2 \vec{X}_2 \succeq_2 \vec{\alpha}'_2 \vec{X}_2$, this creates a contradiction.

In the second case in which $\vec{\alpha}_2$ and $\vec{\beta}_2$ are not comparable by majorization. This means that $\alpha_1 < \beta_1$ and $\alpha_1 + \alpha_2 > \beta_1 + \beta_2$. But this is impossible since, by assumption, we have $\alpha_1 + \alpha_2 = \beta_1 + \beta_2 = 1$. Thus, $\vec{\beta}_2$ must majorize $\vec{\alpha}_2$ and the necessary part of this theorem holds. \square

Appendix 3 : Proof of Theorem 7

As $\vec{\beta}_n \succeq_M \vec{\alpha}_n$, by Theorem 1, there exist $\vec{\alpha}_n^i = (\alpha_1^i, \dots, \alpha_n^i)'$ ($0 \leq i \leq k$) with $k \leq n - 1$ such that $\vec{\alpha}_n = \vec{\alpha}_n^0 \xrightarrow{d} \dots \xrightarrow{d} \vec{\alpha}_n^i \xrightarrow{d} \vec{\alpha}_n^{i+1} \xrightarrow{d} \dots \xrightarrow{d} \vec{\alpha}_n^k = \vec{\alpha}_n$. For any two consecutive vectors in $\{\vec{\alpha}_n^i\}$, say $\vec{\alpha}_n^i$ and $\vec{\alpha}_n^{i+1}$, there exist h and k ($1 \leq h < k \leq n$) such that $\alpha_j^i = \alpha_j^{i+1}$ for any $j \neq h, k$; $\alpha_h^i = \alpha_h^{i+1} - \epsilon$; and $\alpha_k^i = \alpha_k^{i+1} + \epsilon$ with $\epsilon > 0$.

Thus, to obtain the proof of this theorem, it is sufficient to prove $\vec{\alpha}_n^{i'} \vec{X}_n \succeq_2 \vec{\alpha}_n^{i+1'} \vec{X}_n$. Nonetheless, this could be obtained by simply applying Theorems 3 and 5 and thereby the assertion follows. \square
